

## **SAP BW Query & Report Element**

A BW query is implemented in HANA Studio. The query definition is stored in the DB system environment. The approach is to consume the data from the underlying base tables and display the report definition with a report.

### **Approach**

Alike the BW Content Model the same approach is used. Instead of aDSO inbound layer objects the source are directly the HANA DB tables where the query definition are physically stored.

On top the these base tables Calculation Views consume the data. The CV Data Model consumes the CV objects and serves as a source for the Composite Provider (CP). With a report on top of the CP the data of the report definition can be displayed in detail.

### **Implementation**

The Implementation is a simple data import of the respective data model. The Composite Provider and the related report definition can be imported via a transport or created in the HANA Studio directly.
